

JavaScript

- is a scripting language
- is an object oriented programming language
- is functional programming language
- is used for adding dynamic behavior (e.g. clicking a button) in the website
- is loosely typed language
 - there is not type checking
 - the data types are inferred
 - the data types are dynamically assigned
- does NOT support pointers

JS Fundamentals

- **rules**

- the semicolon is optional when one statement is written on one line

```
console.log('this is JS tag in head section')
console.error('this is an error')
```

- semicolon is required when multiple statements are written on one line

```
console.log('this is JS tag in head section');
console.error('this is an error');
```

- conventions
 - use camel case when declaring function, variables or classes
 - i.e. start the name with lower case and use upper case for first letter of meaningful word
 - e.g.
 - firstName
 - printPersonInfo()

- **variable**

- is a placeholder to store a value in memory
- it is a mutable
- to declare a variable use **let** keyword
- the variable must be declared without a data type
- e.g.

```
let firstName = "steve"
let salary = 10.60

let age = 40
```

```
// can update the value  
age = 41
```

- **constant**

- is a placeholder whose value **CAN NOT** be changed
- this is immutable (readonly)
- to declare a constant use **const** keyword
- the constant must be declared without a data type
- e.g.

```
const pi = 3.14  
  
// can not update the value of a constant  
// pi = 100
```

ALWAYS TRY TO PREFER CONSTANT THAN A VARIABLE

- **pre-defined objects**

- console
 - object that represents the browser console
 - methods
 - log() : used to print debugging messages on the browser's console
 - info() : used to print information on the browser's console
 - warn() : used to print warning messages on the browser's console
 - error() : used to print error on the browser's console
- window
 - object that represents the browser's window (UI)
 - this is a default object used when calling a method
 - methods
 - alert() :
 - prompt() :
 - confirm() :

- **Pop ups**

- alert
 - used to show a message to the user on web browser's window
 - e.g.

```
// window.alert('this is an alert')  
alert('this is an alert')
```

- prompt

- used to take an input from user
- e.g.

```
const username = window.prompt("Enter your name")
console.log("user name = " + username)
```

- confirm

- used to get input in terms of boolean answer to a question
- e.g.

```
const answer = window.confirm("Do you want to have
break?")
if (answer) {
  console.log('lets take a break of 10 minutes')
} else {
  console.log('lets continue')
}
```

- pre-defined values

- undefined

- NaN

- Not a Number
- NaN has data type as number
- does not represent a valid number
- e.g.

```
// NaN
console.log(10 * 'test1')
```

- Infinity

- has a data type as number
- e.g.

```
// Infinity
console.log(`10 / 0 = ${10 / 0}`)
```

- data types

- all data types in javascript will be inferred
- the data type will be decided by JavaScript by inspecting the current value in the variable
- types

- **number**

- represents whole numbers and floating point (decimal) numbers
- e.g.

```
// number
let num = 100
console.log('data type of num = ' + typeof(num)) // number

// number
let salary = 10.50
console.log('data type of salary = ' + typeof(salary)) //
number
```

- **string**

- collection of characters
- string can be declared using
 - single quotes (')
 - double quotes (")
 - back quotes (`)
- e.g.

```
// string
let firstName = 'steve'
console.log('data type of firstName = ' +
typeof(firstName)) // string

// string
let lastName = "Jobs"
console.log('data type of lastName = ' +
typeof(lastName)) // string

// string
let address = `
    address line 1,
    address line 2,
`
console.log('data type of address = ' +
typeof(address)) // string
```

- **boolean**

- represents only true or false values
- e.g.

```
// boolean
let canVote = false
console.log('data type of canVote = ' +
typeof(canVote)) // boolean
```

- **undefined**

- in JS, undefined is both: data type as well as pre-defined value
- represents a variable without having initial value
- e.g.

```
// undefined
let myvar
console.log('myvar = ' + myvar) // undefined
console.log('data type of myvar = ' + typeof(myvar))
// undefined
```

- **object**

- **statements**

- the smallest unit that executes
- types
 - assignment
 - declaration
 - comment

- **operators**

- mathematical operators
 - addition (+)
 - the plus operator works as
 - mathematical addition when both params are numbers

```
// 30
console.log(10 + 20)
```

- string concatenation operator when one of the operands is a string

```
// test1test2
console.log('test1' + 'test2')
```

- when one of the operands is a string and other is not a string, then all the params get converted to string data type

```
// 1020
console.log(10 + '20')
```

- division (/)
 - mathematical division
 - e.g.

- multiplication (*)
 - mathematical multiplication of two operands
 - the answer will be always a number
 - e.g.

```
// 200
console.log(10 * 20)

// NaN
console.log('test1' * 'test2')

// 400
console.log('10' * 40)

// 400
console.log('10' * '40')
```

- modulo (%)
- subtraction (-) :
- comparison operators
 - double equals to (==)
 - also known as value equality operator
 - checks ONLY the values of operands
 - e.g.

```
// true
console.log(50 == 50)

// true
// '50' is having a value of 50
console.log(50 == '50')
```

- triple equals to (===)
 - also known as identity equality operator
 - checks both the value as well as the data types of the operands
 - always prefer === over ==
 - e.g.

```
// true
console.log(50 === 50)

// false
// 50 is a number while '50' is a string
console.log(50 === '50')
```

- not equals to (!=) :
- not equals to (!==) :
- less than (<) :
- greater than (>) :
- less than equals to (<=) :
- greater than equals to (>=) :
- logical operators
 - and (&&) :
 - or (||) :

- **type conversion**

- anything to string
 - any data type can be converted into string by concatenating with plus operator
 - e.g.

```
// '10'
```

```
console.log(10 + '')
```

- string to number

- parseInt

- convert string to integer number (by discarding the decimal precision)
 - e.g.

```
// 10
console.log(parseInt('10'))

// 10
console.log(parseInt('10.60'))

// 10
console.log(parseInt('10test'))

// NaN
console.log(parseInt('test10'))
```

- parseFloat

- convert a string to a decimal number (by keeping the decimal precision)
 - e.g.

```
// 10
console.log(parseFloat('10'))

// 10.60
console.log(parseFloat('10.60'))

// 10
console.log(parseFloat('10test'))

// NaN
console.log(parseFloat('test10'))
```

- **function**

- a block of code which can be reused
 - reusable block of code having a name
 - types
 - empty function

- function with no code in the body
- e.g.

```
// empty function
function function0() {}
```

- parameterless function
 - which does not accept any parameter
 - e.g.

```
// parameterless function declaration
function function1() {
    console.log('inside function1')
}

// function call
function1()
```

- parameterized function
 - which accepts at least one parameter
 - e.g.

```
function function2(param) {
    // param = true
    console.log(`inside the function2`)
    console.log(`param = ${param}, type of param =
    ${typeof(param)}`)
}

function2(20)
function2('test1')
function2(true)
```

- **variable length argument function**
 - a function which can accept variable length of arguments
 - every function in JS receives a hidden parameter named arguments
 - which contains a list of all the arguments passed while the function call
 - e.g.

```
function add() {  
  // console.log('inside add')  
  console.log(arguments)  
  
  let sum = 0  
  for (let index = 0; index < arguments.length;  
index++) {  
    sum += arguments[index]  
  }  
  console.log(`addition = ${sum}`)  
}  
  
add(10, 20)  
add(10, 20, 30)  
add(10, 20, 30, 40)
```

- parameters

- the parameter(s) of a function can not have static data type(s)
- the number and type of parameters will be controlled by the caller instead of the function
- caller can pass
 - same number of parameters
 - less number of parameters than expected
 - the missing arguments will be treated as undefined
 - more number of parameters than expected
 - the extra parameters will be discarded
- every function in JS receives two hidden parameters
 - **arguments**: used to get all the arguments in an array
 - **this**: used to point the current object
 - **this** points to window in a function inside javascript in html
 - **this** points to Object if called outside the html
- e.g.

```
function function1(n1, n2) {  
  console.log('inside function1')  
}  
  
// n1 = 10, n2 = 20  
function1(10, 20, 30)  
  
// n1 = 10, n2 = 20  
function1(10, 20)
```

```
// n1 = 10, n2 = undefined
function1(10)

// n1 = undefined, n2 = undefined
function1()
```

- default parameters
 - also known as optional parameters as you may not pass the value to these parameters
 - one or more parameters may be declared with a default value
 - the default value will be used if the caller has not passed the argument for the optional parameters
 - e.g.

```
function multiply(num1, num2 = 10) {
  const multiplication = num1 * num2
  console.log(`multiplication = ${multiplication}`)
}

// num1 = 40, num2 = 100
multiply(40, 100)

// num1 = 40, num2 = 10
multiply(40)
```

- function alias
 - giving a function another name
 - same function can be called with original function or the function alias
 - e.g.

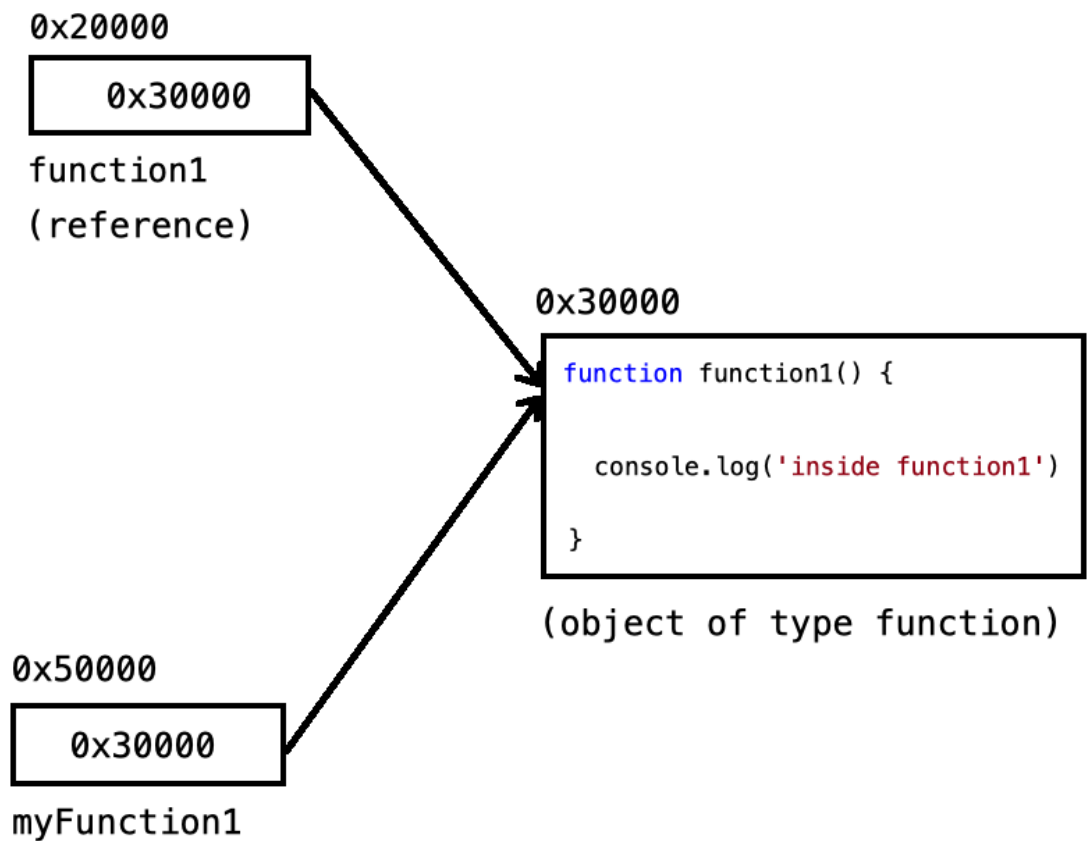

```
function function1() {
  console.log('inside function1')
}

// calling the function1 by its original name
function1()

// function alias
const myFunction1 = function1

// calling the function1 by its function alias
myFunction1()
```

```
function function1() {  
    console.log('inside function1')  
}
```

```
const myFunction1 = function1
```

- **collection**

- collection of values (similar to array of values in C and C++)
- properties
 - **length**
- methods
 - **push**
 - used to append a value at the end of the collection
 - e.g.

```
const numbers = [10, 20, 30]  
  
// [10, 20, 30, 40]  
numbers.push(40)
```

- **html + JS**
- **predefined functions**
 - `typeof()` : used to get the data type of a variable

JS as functional programming language

- in JS, function is considered as first class citizen
 - function can be called by passing another function as an argument
 - a variable can be created for a function (function alias)
 - a function can be considered as a variable
 - one function can be considered as a return value of another function

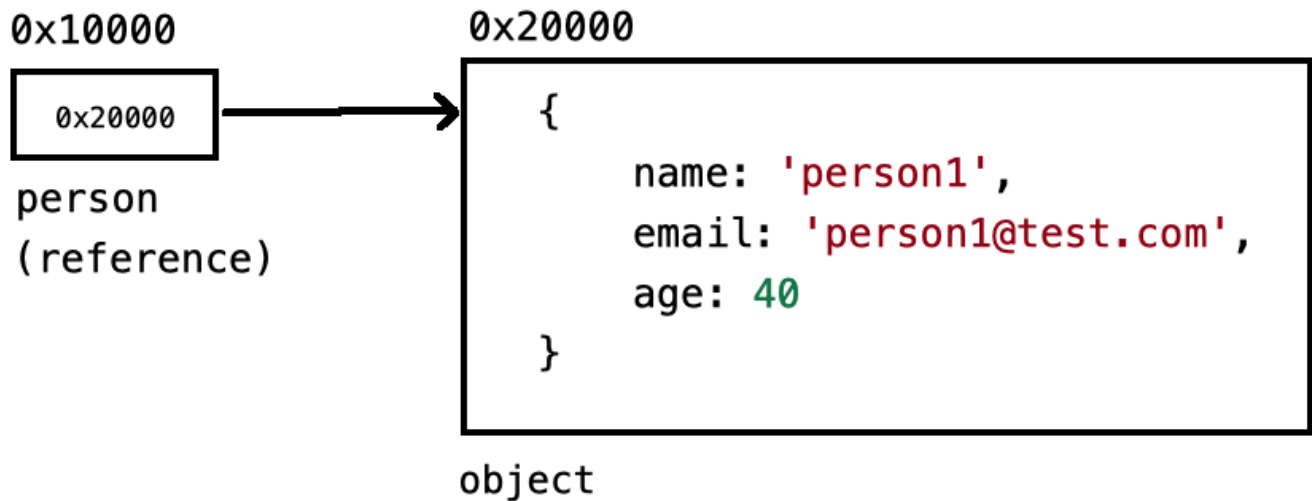

OOP JS

- JS is object oriented programming language
- object can be created by
 - using JSON
 - using Object
 - using constructor functions
 - using keyword class

object

- similar to instance of a class in other language
- collection of key-value pairs
- keys are also known as properties
- e.g.

```
const person = {  
  name: 'person1',  
  email: 'person1@test.com',  
  age: 40  
}  
  
// properties - name, email, age  
// values     - person1, person1@test.com , 40
```

- to access value of a property
 - use subscript ([]) syntax
 - used when a property is having special character like space
 - e.g.

```
console.log(`name: ${p1['name']}`)  
console.log(`email: ${p1['email']}`)  
console.log(`age: ${p1['age']}`)
```

```
const person = {  
  'first name': 'steve',  
  'last name' : 'jobs'  
}  
  
console.log(`first name = ${person['first name']}`)  
console.log(`last name = ${person['last name']}`)
```

- use dot (.) syntax
 - e.g.

```
console.log(`name: ${p1.name}`)  
console.log(`email: ${p1.email}`)  
console.log(`age: ${p1.age}`)
```

- can not be used when a property has a special character like space

JSON

- JavaScript Object Notation
- way to create an object
- JSON supports
 - object
 - collection of key-value pairs
 - e.g.

```
const person = {  
  name: 'person1',  
  email: 'person1@test.com',  
  age: 40  
}
```

- array
 - collection of objects
 - e.g.

```
const persons = [  
  { name: 'person1', email: 'person1@test.com' },  
  { name: 'person2', email: 'person2@test.com' },  
  { name: 'person3', email: 'person3@test.com' },  
  { name: 'person4', email: 'person4@test.com' }  
]
```

creating object using Object

- Object is a root function provided by JS
- everything in JS is an Object
